

ABSTRACT

Method and apparatus for selecting rendering intent including computer program product. A set of rendering intents, and a colored document or image is received. A set of rendered images are created and simultaneously previewed by rendering the received image according to the received rendering intents. Alternatively, a set of rendered differences are created from the rendered images and simultaneously previewed. Difference images reflect differences between rendered images and a reference image. Reference images can be either the source image or another rendered image. Rendered images or differences are simultaneously previewed by simultaneously displaying them on a monitor, or by printing them on a single sheet of paper. A rendered image or difference is selected by user input. The rendered images or difference images are associated with a rendering intent. The associated rendering intent is selected to render the received document or image.
